**Abstract** A network of over 100 Global Stratotype Sections and Points (GSSPs) is being established by the International Commission on Stratigraphy, a Commission of the International Union of Geological Sciences. This network of sites, about 60% of which are already ratified, relates to all the stage, system and series boundaries of the geological column and thus provides the fundamental basis for the geological timescale and the history of planet Earth. Given the importance of these sites and the work that has been ongoing by the international geological community since 1977 to select and ratify the sites, their long-term conservation is essential, yet in most cases, there is no legislative protection for them and no international recognition, beyond the geological community, of their importance. The two existing international conservation networks used to protect geological sites/areas (World Heritage Sites and Global Geoparks) are both unsuitable for the conservation of the GSSP network, and instead a case is made in this paper that UNESCO, in collaboration with other organisations, should establish a third internationally recognised geoconservation network for the complete GSSP site series.

## Introduction

The general demise of the International Union of Geological Sciences' (IUGS) project to establish a Global Geosites network means that there are currently only two international

site/area networks that recognise geoheritage values and encourage their geoconservation—World Heritage Sites and Global Geoparks.

World Heritage Sites are recognised under the World Heritage Convention, which is concerned with “protecting the world’s cultural and natural heritage”. The Convention was adopted by the General Conference of UNESCO in 1972, and to date, more than 185 countries have ratified it, making it an important international conservation instrument. A requirement for inscription on the World Heritage List is that the sites are appropriately managed by national and/or local governments and organisations so that their outstanding international heritage values are retained and maintained for future generations. As of November 2010, there are 911 sites on the List in 151 countries, but less than 100 are recognised for their earth science value (e.g. Dingwall et al. 2005). The vast majority are located in developed regions of the world, particularly in Europe, and there is also imbalance between the number of cultural (704) and natural (180) sites (there are also 27 mixed sites). As a result, in 1994, UNESCO launched a Global Strategy for a “representative, balanced and credible” World Heritage List. The aim was, and is, to identify and fill the major gaps, thematic and spatial, in the List. In relation to geological and geomorphological sites, the International Union for the Conservation of Nature (IUCN) carried out a study of existing sites (Dingwall et al. 2005). One of their analyses demonstrated some significant gaps in the representation of the geological column, particularly the absence of sites in the Silurian and Cenozoic, whilst another identified the low number of stratigraphic sites. One of the aims of this work was to assist the World Heritage Committee and its advisors to identify possible gaps in the coverage of the World Heritage List so as to encourage countries to nominate sites that might help fill these gaps.

The Global Network of National Geoparks (Global Geoparks) was established in 2004 and is a rapidly growing international network of areas recognised for their geoheritage values. The network is supported by UNESCO but is not yet a fully recognised UNESCO programme. The three aims of Global Geoparks are conservation of the geopark's geoheritage, geological education and sustainable economic development mainly through geotourism. There are currently (November 2010) 77 members of the network in 24 countries, but most are in China (24) and Europe (42).

This paper draws attention to a third important, but less well known, geoheritage site network where international recognition and action is urgently required in order to try to secure its conservation—Global Stratotype Sections and Points (GSSPs).

### Global Stratotype Sections and Points

The International Commission on Stratigraphy (ICS), a commission of the IUGS, has a programme to reach international agreement and definition of all the main stratigraphic boundaries within the geological timescale. The result will be a global network of over 100 GSSPs. The history, philosophy and application of the concept of GSSPs was reviewed by Walsh et al. (2004). The programme commenced in 1977 and is still ongoing with full documentation of ratified sites being published, mainly in the IUGS journal *Episodes*.

The requirements for GSSP status were outlined by Remane et al. (1996) and have subsequently been amended by the ICS. They include:

- stratigraphic completeness across the GSSP level;
- adequate thickness of section above and below;
- continuous sedimentation;
- absence of synsedimentary, tectonic or metamorphic disturbance;
- abundance and diversity of well-preserved fossils;
- support from magnetostratigraphy, chemostratigraphy and dating to increase the possibilities of global correlatability;
- accessibility, including logistics, national politics and property rights; and
- provisions for conservation and protection.

This last point is discussed below.

Table 1 gives a full list of the 115 stratigraphic boundaries in the geological column. Twelve of these in the Precambrian are defined chronometrically (Plumb 1991) and will remain so, and thus have no terrestrial rock record that may be lost or damaged. That leaves 103 GSSPs to be defined on the basis of lithostratigraphy, but this includes the Pleistocene/Holocene boundary as identified in the North GRIP ice core from Greenland (Walker et al. 2008) archived in the University of Copenhagen, Denmark, and possibly some others defined in cores. Thus, there is a maximum of 102 GSSPs that are, or will be, defined on the basis of field outcrops. Of these, 61 had been ratified up to 17 September 2010 (Subcommission for Stratigraphic Information web site: <https://engineering.purdue.edu/Stratigraphy/gssp/>). Of the remaining 41, two have ratified temporary chronostratigraphic boundaries that will be replaced eventually by GSSPs. For the other 39, agreement has yet to be reached, though in most cases, there are shortlists of one or more candidate GSSPs. For example,

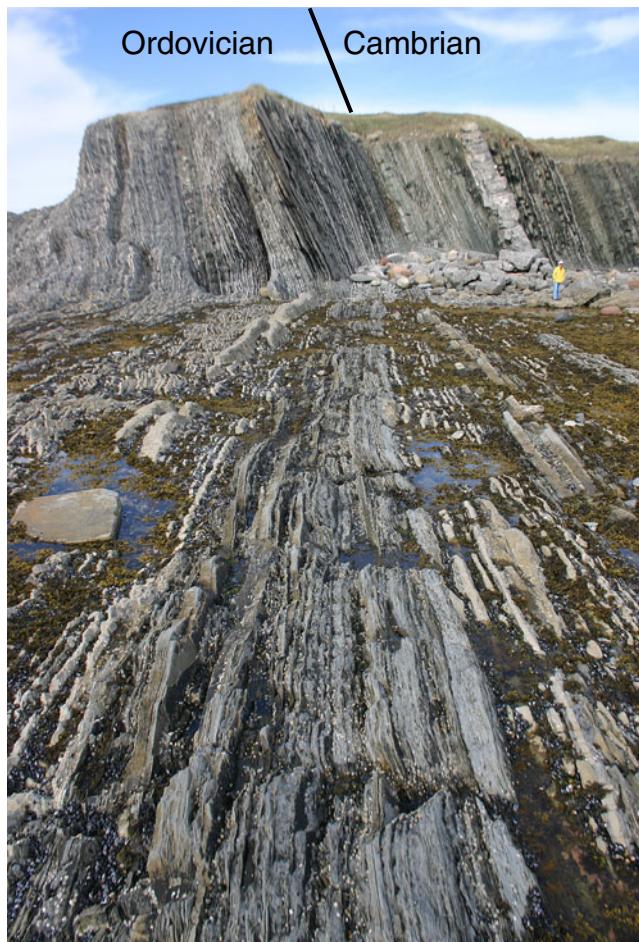

there are three candidate GSSPs (in Poland, USA and Germany) for the base of the Coniacian. The most important sites (Series boundaries in the Cenozoic, System boundaries in the Mesozoic and Palaeozoic) are highlighted in Table 1.

Clearly, these sites are of crucial importance to international stratigraphy and ought to be retained for the future and thus need to be protected from loss or damage (though not from natural processes that retain exposure of the outcrops). Whilst inclusion on the GSSP list clearly identifies the scientific importance of these sites, it does not provide any legislative protection. This has to be the responsibility of the countries or regional/local authorities in which the sites are located. Some GSSPs do have protection through national legislative programmes. For example, Dobb's Linn in Scotland, the GSSP marking the Ordovician/Silurian boundary, is a Site of Special Scientific Interest with protection through the UK's *Countryside & Rights of Way Act* (2000). Similarly, the Precambrian/Cambrian boundary at Fortune Head, Newfoundland, Canada, was designated as an Ecological Reserve in 1992. Also on Newfoundland, the GSSP marking the Cambrian/Ordovician boundary (Cooper et al. 2001) at Green Point (Fig. 1) lies within Gros Morne National Park and is therefore protected by the Parks Canada legislation and the Gros Morne National Park Management Plan. On the other hand, most of the GSSPs in the developing world and even several in the developed world are currently unprotected. For example, of the nine GSSPs currently ratified in Italy, only two are protected, including the Eocene/Oligocene boundary at Massignano (Ancona) located within the Regional Park of Monte Conero. All the others are not protected and some are in a poor condition. Similarly, the GSSP for the base of the Middle Jurassic Series and Aalenian Stage at Fuentelsaz, Guadalajara, Spain, has no legal protection (Carcavilla et al. 2009) other than the Spanish laws requiring permissions from the regional government before any palaeontological sampling can be carried out (Page et al. 2008).

Remane et al. (1996), in their revised guidelines for the establishment of GSSPs, recommended (p. 80) that:

When making a formal submission to ICS, the concerned Subcommission should try to obtain guarantees from the respective authority concerning... permanent protection of the site....ICS should attempt to finalise, within 3 years after IUGS ratification, any remaining official steps for the protection of the site with the authorities of the country in which the GSSP is located.

There are two points to be made about these statements. First, several GSSPs were ratified prior to these 1996 recommendations for geoconservation. Secondly, the reports on most GSSPs ratified after 1996 give little or no information

**Fig. 1** GSSP for the Cambrian/Ordovician boundary at Green Point, Newfoundland, Canada

about the geoconservation status of the sites. But as Page (2004) points out, the establishment of GSSPs is a conservation-driven activity in itself since the intention is to select key sites that will exist into the future as stratigraphic reference points. It follows from the above discussion that not enough attention has been given to the crucial need for conservation of GSSPs. But how should this be achieved?

### Conservation of GSSPs: the way forward?

The lack of effective protection for most GSSPs is a serious matter given their scientific importance to geology and the time and effort expended by the ICS and IUGS to identify, agree and ratify the sites since 1977. Without adequate protection, GSSPs will remain vulnerable to activities that may damage or even destroy them (Page 2004). Whilst it must remain the responsibility of nation states to protect sites within their territories, international recognition of their standing and importance would help bring the importance of the GSSP network to the attention of national

governments and other authorities. However, the two existing international site programmes aimed at geoconservation are unsuitable to be applied to the GSSP network for the reasons outlined below.

One possibility that has been suggested is that the GSSP site network could be established as a serial World Heritage Site. Serial sites are those where a number of individual sites with a common theme are linked together as one serial World Heritage site. An example is the Cornwall & West Devon Mining Landscape in the UK that comprises ten individual mining areas as one serial World Heritage Site. However, it should be noted that these are within the same region of a single country. Given the number and widespread global distribution of GSSPs and the requirement for their management, a single serial GSSP World Heritage Site seems an unlikely and unworkable outcome. Another possibility is that groups of sites could be proposed as serial World Heritage Sites, and this has indeed been suggested by Page et al. (2008) for the 11 Jurassic GSSPs. Not all of these have yet been agreed and ratified, and there would again be the need for coordination between several countries. Page et al. (2008) point out that most of these are in Europe and this project may yet become the ultimate goal for the International Subcommission on Jurassic Stratigraphy. However, not all the other Subcommissions are likely to be able to follow suit, and thus, this approach is unlikely to provide the full consistency and impact that global recognition for the whole network would bring.

On the other hand, the Global Geopark programme is certainly unsuitable as geoparks normally comprise substantial territorial areas within which there may be several geosites rather than the individual sites of limited extent represented in the GSSP network.

Consequently, it is proposed here that the best approach would be for the ICS, IUGS, IUCN and UNESCO to work together to establish a third geoconservation site network, namely a separate GSSP network to sit alongside the World Heritage and Geopark programmes. This would have several benefits. For example, it would create a strong, unified and consistent network recognised by UNESCO that would publicise the importance of these sites to national governments and encourage them to provide legislative and/or other protective/management methods for the sites. It would avoid individual Subcommissions of the ICS from the considerable effort involved in achieving World Heritage status for their site groups. It would also assist UNESCO and the IUCN in their efforts to achieve a series of sites representative of the geological column. Here is a network of sites that has already been subject to rigorous selection processes and comprehensive international

scrutiny by geological experts and finally to ratification by the IUGS, an organisation that already advises UNESCO on applications for World Heritage and Global Geopark status. Thus, there can be no question about the integrity of the network already established and there would be only very limited resource implications for UNESCO. But in recognising this third site network, UNESCO would achieve immense benefits in bringing international attention to the set of sites that define the fundamental basis of the geological history of the planet.

However, this proposal is unlikely to be quickly adopted by UNESCO which has still to fully commit to adopting Global Geoparks as a full UNESCO programme. Nonetheless, when and if that adoption takes place, the next step for international geological and geoconservation community should be to vigorously promote the GSSP network as a new UNESCO programme. In the meantime, pressure should be exerted by national geological communities supported if possible by the ICS, IUGS, IUCN and UNESCO to persuade governments or regional/local authorities to give legal protection to individual GSSPs within their territories.
